

REMARKS

Claims 18-29 and 33-43 are pending. Claims 18, 21, 24, 27, 33 and 36-38 are examined and stand rejected.

Information Disclosure Statements

Applicants previously requested the Office to acknowledge PTO SB/08 submitted with the Information Disclosure Statements of September 4, 2008 and April 3, 2009. Although made of record in PAIR, the Forms remain unacknowledged.

Applicants again request that the Office acknowledges PTO Forms SB/08 submitted with the Information Disclosure Statements of September 4, 2008 and April 3, 2009 and made of record in PAIR.

Response to Rejection of the Claims Under 35 U.S.C. § 103(a)

Claims 18, 21, 24, 27, 33, and 36-38 stand rejected under 35 U.S.C. § 103(a) as allegedly being unpatentable over Lang, Sanigorski, and Yazawa in view of Makula and Koffas for reasons of record.

Briefly, the Office Action relies on Lang as teaching a microbial biomass such as *M. gryphiswaldense* containing an abundance of phosphatidylethanolamine (PE) in the magnetosome membrane (MM) of the microbe.

The Office cites to Yazawa as indirectly establishing the connection between a microbial phospholipid such as PE and the art known anti-cholesterolemic component, eicosapentaenoate (EPA).

Sanigorski is cited by the Office as establishing the nexus between the teachings of Lang and Yazawa, i.e. why one of ordinary skill in the art would be motivated to extract the lipids of Lang which allegedly contain EPA as taught by Yazawa. In this connection, the Office alleges

that Sanigorski teaches the beneficial effects of the administration of EPA in animals. Thus, according to the Office, one of ordinary skill in the art would be motivated to extract PE from the biomass of Lang to reduce cholesterol in animals.

Makula and Koffas are cited as teaching the limitations of claims 24, 27 and 36-38 for reasons set forth in the Office Actions dated August 19, 2008 and May 22, 2009.

The Office Action concludes that one having ordinary skill in the art would have recognized that the procedure of extracting the microbial lipids from the microbial biomass of Lang, would reasonably aggregate EPA-containing phospholipids (as taught by Yazawa), which would result in lowering of the cholesterol levels of subjects ingesting the particular component.

Applicants respectfully traverse and submit that the Office's characterization of the art is misleadingly oversimplified and technically unsupported.

When properly contextualized, Applicants submit that the Office has not established why one skilled in the art would be motivated to combine or modify the teachings of Lang, Sanigorski, Yazawa, Makula, and Koffas to produce the claimed invention. Accordingly, without properly making such a showing, the Office has not established a *prima facie* case of obviousness.

The crux of the rejection is that the cited prior art teaches a biomass containing PE and other nutrients but the art does not expressly equate the lipid extract (PE) of the biomass with reducing hypercholesterolemia. See bottom of page 8 bridging page 9 of the Office Action.

This lack of teaching that biomass PE and PDE are equivalent is a major deficiency in the rejection. Furthermore, this deficiency is exacerbated by the teachings of the present specification, which clearly show that "microbial phospholipids ... would be expected to increase plasma cholesterol." See Specification, page 5, lines 17-22. That the present invention

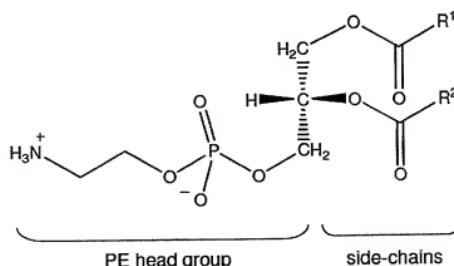

teaches an unknown medical utility is surprising; that the present invention teaches an unknown medical utility that defies conventional teachings at the time of filing is altogether unexpected.

But even this level of technical characterization oversimplifies critical teachings of the art that undercut the Office's reasons for combining the references.

In the present Action, the Office attempts to address this major deficiency by relying on circumstantial evidence based on the teachings of Yazawa and Sanigorski to draw a nexus between the biomass of Lang and reducing cholesterol and LDL:HDL.

Essentially, it is the Office's position that (1) PE is an EPA-containing phospholipid used in feeds (Yazawa); and (2) EPA administration is useful in lowering cholesterol levels in animals (Sanigorski). It is in this regard that Applicants respectfully submit that the Office's characterization of the references is unquestionably unsupported.

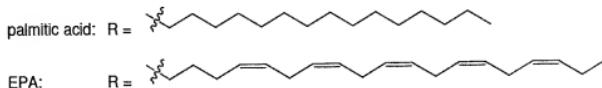

With regard to (1), Applicants preliminarily submit that phosphatidylethanolamines do not have to include EPA as fatty acid components. Specifically, PEs, as with phospholipids in general, are comprised of two parts - a PE "head" group attached to fatty acid side-chains. This concept is illustrated as follows:

where R^1 and R^2 are fatty acid side-chain "tails".

Examples of fatty acid side-chains include palmitic acid (C_{16:0}) and EPA (C_{20:5c,n-3}),

which correspond to the following R-groups.

As is appreciated by one skilled in the art, the nature of the fatty acid side-chains will profoundly affect the cholesteremic response on administration of such a phospholipid to an animal. Not all PEs comprise EPA.

The present invention relates to methods for reducing cholesterol levels in animals by administration of methanotrophic bacterial phospholipids having C₁₄-C₂₂ fatty acid side-chains which are at least 80% by weight saturated or monounsaturated. Further, the phospholipids of the present invention are preferably phosphatidylethanolamines.

In contrast, the cited prior art generally relates to different sorts of phospholipids, i.e. to phospholipids which are not encompassed by the present claims.

Lang discloses PEs in the magnetosome membrane of the bacterium *M. gryphiswaldense*. This bacterium is not a methanotrophic bacterium. Furthermore, the nature of the fatty acid side-chains in the PEs of Lang are not determined. Lange is evidence only of a general bacterial source of PE and is not relevant to the present claims.

Sanigorski and Yazawa both disclose uses of phospholipids comprising EPA in feeds, for example, in the reduction of cholesterol in animals. The EPA-containing phospholipids of Sanigorski and Yazawa are not derived from methanotrophic bacteria. Furthermore, Sanigorski and Yazawa do not relate to phospholipids having side-chains which are >80% wt saturated or monounsaturated.

Of the cited prior art, only Makula relates to methanotrophic bacterial lipids. Makula discloses that methanotrophic bacterial lipids comprise a major portion of phospholipids with C₁₄-C₂₂ fatty acid side-chains which are at least 80% by weight saturated or monounsaturated. Importantly, however, there is no teaching or suggestion in Makula that such lipids may be administered to reduce cholesterol levels in animals.

In summary, the cited prior art does not provide any link between methanotrophic bacterial phospholipids and reduction of cholesterol levels in animals.

At the priority date of the invention, it was known in the art that methanotrophic bacteria comprise a major portion of phospholipids with saturated or monounsaturated fatty acid side-chains. Furthermore, it was also known that the administration of highly saturated fatty acids, e.g. phosphatidylethanolamine-EPA, could lower cholesterol levels.

However, there is no evidence in the cited prior art that methanotrophic bacteria comprise any highly saturated fatty acids in the phospholipid fraction. Neither is there any suggestion in the cited prior art that administration of saturated or monounsaturated fatty acids could reduce cholesterol levels in animals; rather, it was generally believed that administration of such fatty acids would increase cholesterol levels.

It cannot, therefore, have been obvious to one skilled in the art at the time the present application was filed to have selected methanotrophic bacterial phospholipids (comprising no highly saturated fatty acids) for use in methods of reducing cholesterol in animals.

Additionally, in contrast to the Office's position, Yazawa and Sanigorski are neither instructive nor sufficient to support the purported "nexus" linking the biomass of Lang with reducing cholesterol and LDL:HDL. In fact, none of Lang, Yazawa, and Sanigorski teaches the administration of saturated or monounsaturated fatty acids of microbial phospholipids to reduce

cholesterol or LDL:HDL ratios in animals. Furthermore, none of the references teaches PE administration to reduce cholesterol levels or LDL:HDL ratios. At best, the cited art references teach that, in some cases, PE *can* contain EPA (Yazawa), which in turn is associated with arachidonic acid (Sanigorski). However, neither Yazawa nor Lang teaches that a methanotrophic PE, as is presently claimed, contains EPA. Makula is similarly not instructive on the matter, as nothing is mentioned in Makula about containing EPA.

Despite this noticeable absence of disclosure in the art, the Office continues to tenuously rely on Yazawa to assert that the presently claimed methanotrophic PE presumably contains EPA because the PE in Yazawa contains EPA. However, the art simply does not support this correlation. In a separate publication, Yazawa (II)¹ teaches a method for producing EPA-containing phospholipids. The steps comprise isolating cells from the following microbial genera: *Pseudomonas*, *Alteromonas*, *Shewanella*, *Deleya*, *Alteromarinus*, *Pasteurella* or *Vibrio*. Importantly, Lang discloses a *Magnetospirillum* biomass, which is not identified by Yazawa (II) as being capable of producing PE that are EPA-containing.

Yazawa (II) renders suspect the linchpin of the Office's reasoning, i.e. that all PE contains EPA. In view of Yazawa (II), the Office can no longer rely on Yazawa as teaching that methanotrophic PE contains EPA, since Lang's PE was isolated from a genus not identified in the group capable of producing EPA-containing phospholipids. Further still, the data provided in Makula show that the majority of fatty acid side-chains in the phospholipid fraction of methanotrophic bacteria are not highly unsaturated. This conflicts directly with the present

¹ EP App. No. 0404300 A2, attached herewith for instructive purposes.

bacteria, which require the phospholipids to comprise “C₁₄ to C₂₂ fatty acids side chains, which fatty acids are >80% wt saturated or monounsaturated.”

Accordingly, Applicants submit that one skilled in the art would have no reason to extract microbial lipids from the microbial biomass of Lang, because Yazawa (II) teaches that the Lang biomass is not capable of containing an aggregate EPA-containing PE. Further still, assuming *arguendo* that motivation exists to extract PE from Lang for use as a cholesterol reducing agent, one skilled in the art would have no reasonable expectation of success because Yazawa (II) teaches that the Lang biomass is not capable of producing an EPA-containing PE.

For at least the above reasons, Applicants respectfully request withdrawal of claims 18, 21, 24, 27, 33, and 36-38 under 35 U.S.C. § 103(a) over Lang, Sanigorski, and Yazawa in view of Makula and Koffas.

Conclusion

In view of the above, reconsideration and allowance of this application are now believed to be in order, and such actions are hereby solicited. If any points remain in issue which the Examiner feels may be best resolved through a personal or telephone interview, the Examiner is kindly requested to contact the undersigned at the telephone number listed below.

The USPTO is directed and authorized to charge all required fees, except for the Issue Fee and the Publication Fee, to Deposit Account No. 19-4880. Please also credit any overpayments to said Deposit Account.

⑬ Process for production of eicosapentaenoic acid-containing phospholipid and use of said lipid.

EP 0 404 300 ⑭ A process for the production of an eicosapentaenoic acid (EPA)-containing phospholipid, comprising the steps of preparing cells of microorganism capable of producing EPA, extracting the cells with a solvent which can solubilize the EPA-containing phospholipid, removing the solvent to obtain a residue containing the EPA-containing phospholipid, mixing the residue with a solvent which substantially cannot solubilize the EPA-containing phospholipid, recovering the solvent insoluble fraction, and purify the fraction by column chromatography; and a lipid metabolism modifying composition comprising an EPA-containing phospholipid.

PROCESS FOR PRODUCTION OF EICOSAPENTAENOIC ACID-CONTAINING PHOSPHOLIPID AND USE OF SAID LIPID

The present invention relates to a process for the production of eicosapentaenoic acid (abbreviated as EPA thereafter)-containing phospholipid preferably from marine microorganisms, and the use of the lipid, especially as a lipid metabolism modifier. The present phospholipid is also useful in the foodstuff, cosmetics, pharmaceuticals, agriculture, fishing, and chemical industries.

5 Phospholipids are present in various organisms including higher animals and plants, and are responsible for important functions as a component of the cell membrane. The phospholipids industrially produced are soybean phospholipid and yolk phospholipid. These phospholipids are natural surfactants, and their emulsifying action, dispersing action, wetting action, etc. make them useful in the fields of foodstuff, cosmetics, pharmaceuticals and the like. Nevertheless, the soybean phospholipid and yolk phospholipid, as 10 well as other phospholipids of higher animal or plant origin, comprise fatty acids having mainly 16 to 18 carbon atoms, and phospholipids comprising EPA, which has 20 carbon atoms, have not yet been industrially isolated. A process for isolating EPA-containing phospholipid from chlorella (Japanese Unexamined Patent Publication, KOKAI, No. 62-56497) has been proposed, but the growth rate is too low for it to be used as an industrial material from which phospholipid is isolated.

15 The abnormality of the lipid metabolism is partially responsible for "adult" diseases such as arteriosclerosis, thrombosis, hyperlipemia, obesity, hypertension, and diabetes, and although various medicaments have been proposed for the prophylaxis and treatment of these diseases, they do not provide satisfactory results from the viewpoints of pharmacological effectiveness and side-effects, and therefore, there is an urgent need for more effective and safer pharmaceuticals. Recently, EPA has attracted attention, due to its 20 high safety factor, and to date, an EPA in the form of an ethyl ester or triglyceride has been developed. Nevertheless, an EPA linked to phospholipid immediately provides an effect, at a dose of one tenth of the ethyl ester or triglyceride form, and accordingly, a chemical synthesis of EPA-linked phospholipid has been attempted (Japanese Unexamined Patent Publication, KOKAI, Nos. 63-264422 and 58-36215).

This chemical synthesis, however, is disadvantageous in that it is difficult to prevent an incorporation of undesirable impurities, and the cost of the synthesis and purification are high due to a low reaction yield, and thus it is not practically marketable.

Accordingly, the present invention provides a process for the production of an EPA-containing phospholipid, which process can be carried out industrially and efficiently in a short time and with little trouble, and a lipid metabolism modifier comprising EPA-containing phospholipid.

30 More specifically, the present invention provides a process for the production of an eicosapentaenoic acid (EPA)-containing phospholipid, comprising the steps of: preparing cells of microorganism capable of producing EPA; extracting the cells with a solvent which can solubilize the EPA-containing phospholipid; removing the solvent to obtain a residue containing the EPA-containing phospholipid; 35 mixing the residue with a solvent which substantially cannot solubilize the EPA-containing phospholipid; recovering the solvent-insoluble fraction; and purify the fraction by column chromatography.

Figure 1 represents the relationship between feeds used in Example 1 and changes of blood pressure.

40 The present inventors obtained the following finding concerning a lipid produced by a microorganism capable of producing EPA: (1) a total lipid content of a microorganism capable of producing EPA is as high as 6 to 12%, on the basis of dry matter, and at least 90% of the total lipid is a phospholipid; (2) in the fatty acid composition of the total lipid, the content of EPA is as high as 24 to 40%, and only a fatty acid having a high degree of unsaturation is EPA; (3) a high purity phospholipid can be easily obtained by solvent-45 fractionation of the total lipid; and (4) when total lipid is fractionated into a phospholipid, free fatty acids, quinones and other components, by solvent-fractionation and silica gel column chromatography, the ratio of EPA to the total of fatty acids in the phospholipid is at least 30%.

This means that microorganisms capable of producing EPA are a preferable source of an EPA-containing phospholipid. Moreover, the present microorganisms capable of producing EPA have remarkably 50 higher growth rate than that of many other microorganisms, and therefore, a large amount of microbial cells can be obtained in a very short time. In addition an administration of a EPA-containing lipid or cells of a microorganism capable of producing EPA provides an efficient decrease of lipid in the blood and liver, as well as the weight of adipose tissue in animals.

In the present invention, any microorganisms capable of producing EPA may be used. These

microorganisms belong to, for example, the genus *Pseudomonas*, *Alteromonas*, *Shewanella*, *Deleya*, *Alteromarinus*, *Pasteurella*, or *Vibrio*. The properties of these microorganisms are described in detail in E.P. Application No. 87311372.4 (Publication No. 0273708); and Japanese patent application (Unexamined Application, KOKAI) Nos. 62-49929 (63-216488), 63-49930 (63-216489), 62-49931 (63-216490), 62-156893 (1-2587) and 62-273200 (2-23877).

Microorganisms capable of producing EPA and belonging to the genus *Pseudomonas* include *Pseudomonas putrefaciens* SCRC-2181, SCRC-2201, SCRC-2271, SCRC-2341, SCRC-2451, SCRC-2642, SCRC-2792, SCRC-2878, SCRC-3011, and SCRC-3022. Microorganisms capable of producing EPA and belonging to the genus *Alteromonas* include *Alteromonas putrefaciens* SCRC-2571, *Alteromonas putrefaciens* subspecies *sagamifaciens* SCRC-1162, *Alteromonas lumensas* SCRC-6444, and *Alteromonas xylosum* SCRC-2517. Microorganisms capable of producing EPA and belonging to the genus *Shewanella* include *Shewanella putrefaciens* SCRC-2874.

The above-mentioned microorganisms were deposited with the Fermentation Research Institute Agency of

15 Industrial Science and Technology, Ministry of International Trade and Industry, 1-1-3 Yatabe-machi Higashi, Tsukuba-shi, Ibaraki-ken, Japan under FERM P-Numbers, and transferred to International deposition under the Deposit of Microorganisms for the Purposes of Patent Procedure (Budapest Treaty) under FERM BP-Numbers as follows:

December 17, 1987 FERM BP-1625

Alteromonas putrefaciens subspecies *sagamifaciens* SCRC-1162

February 20, 1987 FERM P-9210

30 December 17, 1987 FERM BP-1626.

The above-mentioned strains for the present Invention may be converted to strains having an eicosapentaenoic acid productivity higher than the original strain, by conventional mutation and selection procedures.

The microorganisms used in the present invention can be preserved by a conventional method, such as 35 on an agar slant medium or by lyophilization. As the agar for culturing the microorganism, any medium in which the microorganism used can grow and produce eicosapentaenoic acid can be used. The medium contains, as a nitrogen source, for example, yeast extract, peptone or meat extract, or a combination thereof. Moreover, the medium may contain, as a carbon source, various kinds of sugar such as glucose, fructose, maltose, and sucrose; organic acids, such as intermediates of the TCA cycle such as citrate, 40 fumarate and pyruvate, other organic acids such as maleate and acetate; and amino acids such as aspartate and glutamate. The medium preferably contains sodium chloride, or sea water or artificial sea water. Note, *Alteromonas putrefaciens*, subspecies *sagamifaciens* require sodium chloride.

In a preferred embodiment of the present Invention, a medium containing 1.0% peptone, 0.5% yeast extract, and 1.5% NaCl in tap water (pH 7.0) is used.

45 The microorganisms of the present invention can be cultured in a liquid medium or on a solid medium. The pH value is 6 to 9, preferably 7 to 8. To obtain a large amount of the cells the microorganism is cultured in a liquid medium by stationary culture, or more preferably, by a shaking culture or aeration-agitation culture, under aerobic conditions. The microorganism is cultured at any temperature at which the microorganism can grow and produce eicosapentaenoic acid. The temperature is preferably 5°C to 30°C, 50 and more preferably, 15°C to 25°C. Culturing is carried out for a period sufficient to produce eicosapentaenoic acid in an amount enough to enable the recovery of EPA-containing phospholipid, preferably for 8 to 48 hours.

The cultured cells are recovered by a conventional procedure such as centrifugation, and dried by a conventional procedure such as lyophilization, spray-dry or drum-dry to obtain a microbial cell powder.

55 Next, to obtain a crude phospholipid fraction, the dried cells are extracted with a solvent, preferably an organic solvent or a mixture thereof which can solubilize phospholipid, such as chloroform/methanol, n-hexane/ethanol/water, chloroform/hexane, chloroform/ether, chloroform/ethanol, or the like.

The extract is then evaporated to remove the solvent, and the resulting residue is subjected to organic

solvent-fractionation. For the fractionation, for example, acetone, acetic acid, chloroform, or ether, such as ethyl ether, is used. The solvent for the fractionation may contain inorganic salts such as magnesium chloride, calcium chloride or the like. The fractionation is usually carried out by mixing the extract residue with a fractionation solvent which cannot solubilize the phospholipid, such as acetone at a temperature 5 -80°C and 40°C, for example at room temperature, and separating an insoluble fraction containing the phospholipid from the solvent.

If necessary, the phospholipid-containing fraction obtained as described above is further purified by column chromatography, to obtain a highly purified phospholipid composition. The column chromatography used is, for example, hydrophobic chromatography, chromatography using a silica-series carrier, 10 chromatography using a polymer gel such as Toyopearl (Tosoh, Japan), and chromatography using octadecyl-linked silica and the like.

The thus obtained phospholipid composition may be analyzed to determine the phospholipid components thereof, by thin layer chromatography using as a solvent system, for example, chloroform/methanol/water. According to the present invention, a phospholipid composition mainly comprises phosphatidylethanolamine and phosphatidylglycerol. The phospholipid composition also may be analyzed to determine the fatty acid content thereof, by saponifying the phospholipid, methylating the saponification product, and analyzing the methylated fatty acids by gas chromatography. For example, the present phospholipid composition contains EPA, oleic acid, palmitoleic acid, palmitic acid, and myristic acid, and trace amounts of other fatty acids.

20 The phospholipid prepared from a microorganism capable of producing EPA, and cells of the microorganism, can be used as a lipid metabolism modifier. The dose of the phospholipid is approximately 1 mg to 1 g of EPA-linked phospholipid/kg body weight/day. Where microbial cells per se are administered, an amount of about 20 fold of the dose of the phospholipid provides approximately the same effect as the phospholipid. Any formulation can be used, but preferable formulations are, for example, capsule, granule, 25 pill, suspension, emulsion, powder, tablet, syrup, and an injectable liquid. These pharmaceutical preparations may contain pharmaceutically or biologically acceptable additives.

The present lipid metabolism modifier can be used not only for pharmaceuticals for the prophylaxis and treatment of human diseases, and of animals such as domestic animals and pets, but also as a component of a health food and of a feed such as chicken feed for the production of low-cholesterol eggs.

30 Next, an example of a composition of feed is shown.

45

The present invention will now be further illustrated by, but is by no means limited to, the following examples.

50

Example 1

55 *Alteromonas putrefaciens* SCRC-2871 (FERM BP-1624), which can produce EPA, was cultured in a medium containing peptone 1%, yeast extract 0.5%, and NaCl 1.5% (pH 7) at 25°C for 18 hours, under an aerobic condition by a 101-jar fermenter, and the cultured broth was centrifuged to collect cells, which were then washed with water and dried by lyophilization to obtain a cell powder. Then 100 g of the cell powder was extracted with 5 l of a mixture of chloroform/methanol (2:1), and the extract was evaporated to obtain 8 g of a lipid extract.

To the lipid was added 400 ml of acetone, the mixture was stirred while cooling, and then filtered to recover an acetone-insoluble fraction. The acetone-insoluble fraction was dried to obtain about 7 g of a phospholipid composition (abbreviated as EPA-PL). The phospholipid component of the EPA-PL was determined by thin layer chromatography, and the fatty acid composition was determined as described above by gas chromatography. As a result, the EPA-PL comprised mainly phosphatidylethanolamine and phosphatidyl-glycerol; and the fatty acid components were EPA, oleic acid, palmitic acid, palmitoleic acid, and myristic acid, and trace amounts of other fatty acids.

The EPA-PL was used in a feed shown in Table 1. As a control, a feed wherein the EPA-PL was replaced by 20% butter was prepared. The EPA-PL feed or the butter feed (control) was administered to 10 SHR-SP rats (stroke-prone spontaneously hypertensive rat, male, body weight 200 g) in an amount of 5 g/day, and a normal feed (SP feed, Funabashi) was also given in an amount of 13 g/day.

The animals were fed for 4 weeks, and during this period, the tail artery pressure was measured at one-week intervals.

After feeding the animals for 4 weeks, they were dissected, and weight of the adipose tissue, the 15 amount of triglyceride in the liver, and the plasma lipid were measured. The liver triglyceride was measured by the acetylacetone method, after an extraction of the total lipid with a chloroform/methanol (2:1) mixture. The plasma total cholesterol was measured by Zukowski method; and VLDL (very low density lipoprotein) and chylomicron were measured by fractionating to each lipoprotein by ultracentrifugation and then measuring the cholesterol content therein by the above-mentioned method. The plasma triglyceride and 20 phospholipid were measured by the acetylacetone method and phosphorus permanganate method, respectively.

The thus-obtained results are shown in Figure 1 and Tables 2 to 4. Note, in Tables 2 to 4, the number in parentheses shows the rate (%) of a decrease of a value calculated by taking the control as 100%.

20 Example 2

A marine microorganism *Shewanella putrefaciens* SCRC-2874 (FERM BP-1625) was cultured in the medium containing meat extract 1%, peptone 1% and NaCl 0.5% (pH 7.0), and the cultured broth was centrifuged to obtain cells, which were then washed and dried to obtain a microbial cell powder, as described in Example 1. Next, 100 g of the cell powder were extracted with a solvent mixture of n-hexane/ethanol/water (2:0.9:0.1), and the extract was evaporated to obtain 12 g of a total lipid. To the total lipid was added 500 ml of acetone, and the mixture was stirred while cooling, and separated into an acetone-soluble fraction containing fatty acids and quinone, and an acetone-insoluble fraction containing the phospholipid. The thus-obtained acetone-insoluble fraction was dissolved in butanol, and fractionated by silica gel column chromatography, using as an eluate butanol/acetic acid/water, as described in Example 1. Each fraction was tested for the presence of the phospholipid, and fractions containing the phospholipid were combined to obtain 10.5 g of a phospholipid composition. The composition contained, as main components, phosphatidylglycerol and phosphatidylethanolamine; and the fatty acid components comprised EPA, oleic acid, palmitic acid, palmitoleic acid, and myristic acid, and trace amounts of other fatty acids.

35 As seen from the above, according to the present invention, there is provided a process for a production of an EPA-containing phospholipid, which process is efficient and makes it possible to isolate and purify the desired phospholipid in a short time, and a safe lipid metabolism modifier.

40 Example 3

A marine microorganism *Pseudomonas putrefaciens* SCRC-2878 (FERM BP-1623) was cultured in the medium containing meat extract 1%, peptone 1% and NaCl 0.5% (pH 7), and the cultured broth was centrifuged to obtain cells, which were then washed and dried to obtain a microbial cell powder, as described in Example 1. Next, 100 g of the cell powder were extracted with a solvent mixture of chloroform/methanol (2:1), and the extract was evaporated to obtain 8 g of a total lipid. To the total lipid was added 400 ml of acetone, and the mixture was stirred while cooling, and separated into an acetone-soluble fraction containing fatty acids and quinone, and an acetone-insoluble fraction containing the phospholipid. The thus-obtained acetone-insoluble fraction was dissolved in chloroform, and fractionated by silica gel column chromatography, using as eluates chloroform, chloroform/methanol (2:1), chloroform/methanol (1:1), and methanol in this order. Each fraction was tested for the presence of the phospholipid, and fractions containing the phospholipid were combined to obtain about 7 g of a phospholipid composition. The composition contained, as main components, phosphatidyl glycerol and phosphatidylethanolamine as determined by TLC; and the fatty acid components comprised EPA, oleic acid, palmitic acid, palmitoleic acid, and myristic acid, and trace amounts of other fatty acids.

Claims

1. A process for a production of an eicosapentaenoic acid (EPA)-containing phospholipid, comprising the steps:
 - of preparing cells of a microorganism capable of producing EPA;
 - extracting the cells with a solvent which can solubilize the EPA-containing phospholipid;
 - removing the solvent to obtain a residue containing the EPA-containing phospholipid;
 - mixing the residue with a solvent which substantially cannot solubilize the EPA-containing phospholipid;
 - recovering the solvent-insoluble fraction;
 - and purify the fraction by column chromatography.
2. A process as claimed in Claim 1, characterized in that the microorganism capable of producing EPA is selected from the group consisting of the genera Pseudomonas, Alteromonas, Shewanella, Deleya, Alteromarinus, Pasteurella and Vibrio.
3. A process as claimed in Claim 2, characterized in that the microorganism of the genus Pseudomonas is selected from the group consisting of Pseudomonas putrefaciens SCRC-2181, SCRC-2201, SCRC-2271, SCRC-2341, SCRC-2451, SCRC-2642, SCRC-2792, SCRC-2878, SCRC-3011, and SCRC-3022.
4. A process as claimed in Claim 2, characterized in that the microorganism of the genus Alteromonas is selected from the group consisting of Alteromonas putrefaciens SCRC-2571, Alteromonas putrefaciens subspecies sgamifaciens SCRC-1182, Alteromonas luteinensis SCRC-6444, and Alteromonas xylosus SCRC-2517.
5. A process as claimed in Claim 2, characterized in that the microorganism of the genus Shewanella is Shewanella putrefaciens SCRC-2874.
6. A process as claimed in any one of Claims 1 to 5 characterized in that the EPA-containing phospholipid comprises mainly phosphatidylglycerol and phosphatidylethanolamine.
7. A process as claimed in any one of Claims 1 to 6 characterized in that the solvent which cannot solubilize a phospholipid is selected from the group consisting of chloroform/methanol mixtures, n-hexane/ethanol/water mixtures, chloroform/hexane mixtures, chloroform/ether mixtures, and chloroform/ethanol mixtures.
8. A process as claimed in any one of Claims 1 to 7 characterized in that the solvent which cannot solubilize a phospholipid is acetone.
9. A lipid metabolism modifying composition comprising an EPA-containing phospholipid.
10. A composition as claimed in Claim 9, characterized in that the phospholipid comprises phosphatidylethanolamine and phosphatidylglycerol.
11. A lipid metabolism modifying composition comprising cells of a microorganism capable of producing EPA.
12. A microorganism capable of producing EPA characterised in that the total lipid content of the microorganism is in the range 8 to 12% on the basis of dry matter, and at least 90% of the total lipid is a phospholipid, the content of EPA in the fatty acid component of the total lipid is in the range 24 to 40% and the only fatty acid present which has a high degree of unsaturation is EPA.
13. A lipid produced by a microorganism capable of producing EPA characterised in that the total lipid content of the microorganism is in the range 8 to 12% on the basis of dry matter, and at least 90% of the total lipid is a phospholipid, the content of EPA in the fatty acid component of the total lipid is in the range 24 to 40% and the only fatty acid present which has a high degree of unsaturation is EPA.
14. The use of cells of a microorganism capable of producing EPA as a lipid metabolism modifying agent in the preparation of a pharmaceutical composition for therapeutic use.
